to build blast furnaces in Novaya Tula, Cherepovets, Lipetsk, and Krivoy Rog was reduced by a new welding method for steel plates. Welding was mechanized up to 70%. Programming to automate the build-up welding of parts having complex shapes such as dies and punches was developed. The Institut metallokeramiki i spetsial'nykh splavov (Institute of Powder Metallurgy and Special Alloys) designed the first USSR powder-metallurgical (cermet) rolling mill of the type PM-2 (PM-2). Theoretical investigations to discover how the electron structure of metals, alloys, and poorly fusible compounds is related to their physicochemical and mechanical properties showed that it is possible to predict the properties of new materials and to produce materials having predetermined properties. Surface properties of liquid metals and alloys, and processes of wetting, penetration, and sintering were investigated. Methods of producing materials able to resist the effects of being in contact with poorly fusible metals up to 2000°C or those of being in zinc melts and zinc gas were developed. The technology of 14 poorly fusible compounds was studied, including the production of thermocouples for measuring temperatures in neutral and reducing media or in vacuo up to 2600°C, and in oxidizing media up to 1500°C. Achievements of the Institut kibernetiki

Utilization of scientific progress ...

(Institute of Cybernetics) in the field of digital computers found practical use in the automation of more than 30 industrial plants. A widely applicable control mechanism and a quick-operating electronic computer were released for series production. The single-phase motors with condenser starter, developed by the Institut elektrotehniki (Electrotechnical Institute), brought down the costs of agricultural electrification by 8-12%. A single-phase network for railroads reduces copper consumption for conductor lines by 50-66% and halves the number of transformers required. The Institut fizicheskoy khimii (Institute of Physical Chemistry) studied the hydrogenation of carbon dioxide and dioxide with a nickel catalyst, the results from which are utilized for purifying a nitrogen-hydrogen mixture from carbon oxide and dioxide in the production of ammonia at the Lisichanskiy khinkombinat (Lisichansk Chemical Combine). The Institut organicheskoy khimii (Institute of Organic Chemistry) established the relations between the structure and the physical properties of synthesized cyanine dyes. Carbocyanines were successful. The relationship between the structure and light absorption of azacyanines was studied. Based on this experience, new dyestuff sensitizers for black-and-white and colored motion-picture films are being

used at the Shostkinskaya fabrika (Shostka Plant). By feeding cows with dry brewer's yeast, the microflora in the rumen was changed so as to increase the fat content of the milk by 0.4%. The criticism is made that sometimes not enough initiative is shown in introducing new achievements, thus the Dnepropetrovskoye parokhodstvo (Dnepropetrovsk Steamship Company) delays the introduction of freight programming developed by the Institute of Cybernetics, and the Kiyevskiy zavod meditsinskikh preparatov (Kiyev Plant of Medical Preparations) has not begun to produce "Mikrotsid", a raw material for producing glucose oxidase. A method of producing photocells developed by the Institut fiziki (Institute of Physics) is not yet used on an industrial scale and the same applies to an infrared spectrograph. Methods developed by the Institut ispol'sovaniya gaza (Institute of Gas Utilization) for heat treatment, infrared drying, and gas heating have not yet found wide application.

TITLE: Plastic deformation of a rotating disc

PERIODICAL: Energomashinostroyeniye, no.3, 1963, 26-28

TEXT: Reference is made to earlier experiments conducted and published by the two junior authors (Energomashinostroyeniye, no.2, 1960 and Teploenergetika, no.12, 1960) in which a carbon steel disc with a center bore was spun up. A radially flexible but torsionally stiff element inside the bore permitted almost unrestrained radial expansion of the disc. The yield stress was defined by a residual strain of 0.2%. The strains in the disc of 365 mm outside diameter and a uniform thickness of 20 mm were measured with wire strain gauges at speeds up to 18000 rpm. Strains are plotted against rpm for several points on the disc. Plastic deformation clearly begins where the plot becomes steep. A correlation is sought with the stress-strain diagram obtained in tensile tests. It is seen that the yield point obtained in

Card 1/2

5/114/63/000/003/005/005
E191/E435

Plastic deformation ...

this experiment, having regard to the stressing conditions and the accepted hypotheses about complex stresses under small elastoplastic deformations, is only slightly lower than the 0.2% residual strain definition. A comparison with an analytical computation in a graph of the spread of the plastic zone along the disc radius plotted against the rotational speed shows that the inner layers of the disc change into the plastic state much later and the outer layers much earlier than in accordance with analysis. The range of rotational speeds wherein the disc is in an elastoplastic state is in fact much smaller than in theory. An explanation is the redistribution of stresses which causes a departure from the linear stress/strain relationship ahead of the yield point. It follows that a safety factor derived as a ratio of the load at which residual stresses appear in the disc to the actual working load may be substantially misleading. It is pointed out that the approach of G. Weiss and V. Prager (Journal of the Aeronautical Sciences, no. 3, 1954) based on a concept by which the entire radial cross-section of the disc moves bodily when the plastic deformation is reached, yields the best results for approximate stressing calculations. There are 5 figures.

TITLE: Fatigue and static crack strength of brittle cermet materials

SOURCE: Nauchno-tekhnicheskoye obshchestvo mashinostroitel'noy promyshlennosti. Tsentral'noye pravleniye. Voprosy mekhanicheskoy ustalosti (Problems in mechanical fatigue), Moscow, Izd-vo Mashinostroyeniya, 1964, 23-45

TOPIC TAGS: fatigue, static crack strength, cermet, brittle fracture, fatigue crack, silicon carbide, chromium carbide

ABSTRACT: This article cites the results of investigations into the static crack strength and fatigue of two classes of cermet materials: those having appreciable porosity and manufactured on a base of ductile components, and materials whose base consists of silicon and chromium carbides. In the investigation of materials having a base of ductile metals (Fe), the porosity was varied, while in the case of materials on a base of carbides, the binder content was varied. Specimens of varying size were tested. It was found that the strength of cermet materials decreased with an increase in their size both at normal and at elevated

Cord 1/3

3163817-65

ACCESSION NR: AT5007857

temperatures. The investigations also showed that the type of loading (bending with a concentrated force, pure bending, extension) had a substantial effect on the strength characteristics, the strength on bending with a concentrated force being higher than with pure bending and the lowest values of the strength characteristics being observed during tension. A characteristic feature of certain brittle cermet materials is their comparative insensitivity to stress concentrations in the complete absence of ductility. All the regularities noted (the considerable scatter of strength characteristics, the effect of absolute size and type of loading on strength, the comparatively low sensitivity to stress concentrations, and the increase in the strength characteristics with increasing temperature) can be explained by statistical theories of strength based on the "weak link" hypothesis, in particular on Weibull's theory. The results from investigations of the effect of loading rates on strength (ranging from 0.01 to 1000 kg/mm² sec) show that the strength of carbide-base materials increases with an increase in loading rate, whereas the strength of iron-base porous materials hardly changes. The static crack strength drops with an increase in porosity. Orig. art. has: 14 formulas, 5 tables and 23 figures.

SOURCE: Medzinárodná konferencia o praskovej metalurgii. 1st, 1962. Problemy praskovej metalurgie: sborník vedeckych prác (Problems in powder metallurgy; collection of scientific papers). Bratislava, Vyd-vo SAV, 1964, 67-82

TOPIC CODE: brittle material, plastic material, property, stress, fracture phenomena 14

ABSTRACT: Metal-powder materials can be divided into two main classes from the standpoint of their mechanical properties: brittle metal-ceramic materials and porous materials made of plastic constituents. The first class of materials is characterized by a considerable dispersion of properties, by the influence of size and sort of stress upon the strength, and by increasing strength with increasing temperature. These facts are in accordance with the results of the statistical theory of strength. Laws governing the fracture phenomena of the second class of materials can be explained taking into consideration the reduc-

tion of cross-sectional area by pores and the heterogeneity of stress in cross section which, as a rule, increases with increasing temperature. Orig. art. has: 21 formulas and 12 figures.

TITLE: Hysteresis energy as the basic criterion of metal failure in cyclic uniaxial thermal loading

SOURCE: AN UkrRSR. Dopovidi, no. 7, 1964, 893-895

TOPIC TAGS: metal fatigue, metal failure, hysteresis energy, metal failure criterion, irreversible absorption energy, elastic hysteresis, stress, strain, deformation, uniaxial thermal loading

ABSTRACT: The basic regularities of thermal fatigue are discussed and formulas for irreversible absorbed energy, hysteresis energy, heating-cooling cycle, total accumulation of irreversible absorbed energy at complete thermal fatigue, and relationship between total accumulation prior to complete thermal fatigue are derived. It is shown that the specific irreversible absorbed energy in the area of the hysteresis loop which takes into account stress and deformation must be considered the basic criterion of metal failure in cycle thermal loading. testing machine

ABSTRACT: An experimental testing chamber for testing the mechanical properties of
high-melting metals in a vacuum and in an inert medium at high temperatures has been
developed (see Fig. 1). The temperature dependence of the modulus of elasticity,
strength limit, and hardness limit of tungsten and molybdenum were determined. The
experimental results are presented graphically (see Fig. 2). It was found that the
strength and hardness limit obeyed the expressions of Frantsevich-Vrontskiy and

TsDM PU-10 testing machine

ABSTRACT: The course of plastic deformations in metals and alloys as a function of
the stresses and number of loading cycles is studied. The work was done to obtain
criteria for the fatigue strength of materials. A system developed earlier by V.
T. Troshchenko (Novyye mashiny i probory dlya ispytaniya metallov, M., Metallurgizdat,
1963) underlies the method. The 10-ton East German TsDM PU-10 machine was used for
mechanical loading of up to $P_a = \pm 49$ kN. The frequency can be varied smoothly from

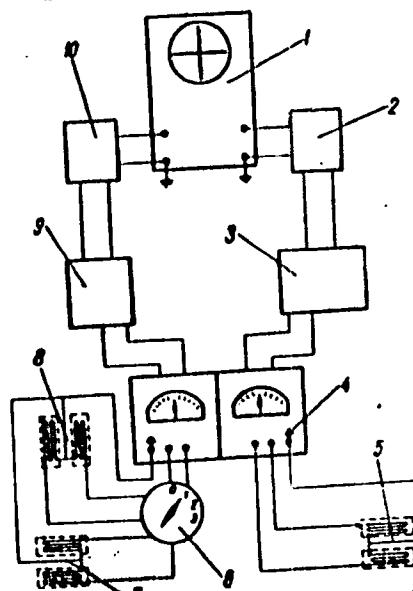

Card 1/3

L 21818-66

Copper and 45, 25, 20Kh, EI726, and 1Kh18N10T steels were tested. (see Fig. 2).

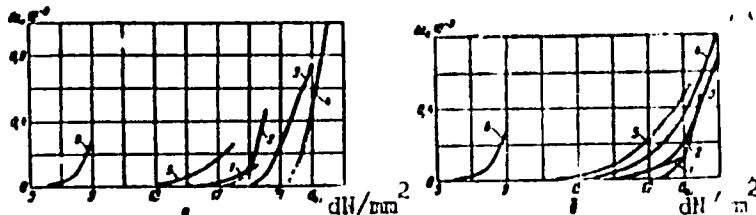

Fig. 2. Change in width of hysteresis loop versus stress: a - first loading; b - second loading; 1 - EI726; 2 - 25 steel; 3 - 20Kh steel; 4 - 45 steel; 5 - 1Kh18N10T steel; 6 - copper.

With cyclic stress and strain, opening of the hysteresis loop for the steels tested is observed with much smaller stresses than with static loading. For the steels, with stresses exceeding the fatigue limit, the width of the hysteresis loop increases regularly with the number of loading cycles until destruction of the specimen. Orig. art. has: 2 diagrams, 3 graphs, 2 photographs, 2 tables, and 4 formulas.

turbine and pump disks

SOURCE: AN UkrSSR. Dopovid, no. 9, 1965, 1157-1160

TOPIC TAGS: turbine disk, disk opening, stress concentration, stress
calculation, stressABSTRACT: Theoretical formulas presently used to calculate the stress
concentration around circular openings located in a rotating turbine
or a pump disk at a distance from its center are analyzed and compared
with formulas derived from experimental data. Theoretical values of
the stress-concentration factor were as much as 30—34% lower than the
experimental values, regardless of the diameter of the openings or
their distance from the disk center or rim. On the basis of the
experimental data, corrective coefficients for calculating the radial
and tangential stress concentrations were derived which reduced the
difference between the theoretical and experimental values of the
stress concentration factor.

090106-1

L 5437-61

ACC NR: AP5024782

stress concentration to 17—30%. Thus even improved formulas cannot be used to calculate all the factors which affect the stresses near an eccentric opening. Thus it can be concluded that in an operating rotating turbine or pump disk, a maximum stress concentration can appear at any point of an eccentric opening, depending on the location of openings and the effect of various other factors. TITLE: Effect of cyclic plastic deformation on metal fatigue under conditions of homogeneous and nonhomogeneous stress states.

SOURCE: Prikladnaya mekhanika, v. 1, no. 1, 1965, 52-61

TOPIC TAGS: plastic deformation, fatigue strength, steel, copper, tensile strength, compression strength, shear strength/ 20Kh steel, 25 steel, 45 steel, 1Kh18N9T steel, 1Kh18N10T steel, EI726 steel, TsDM PU 10 hydraulic machine

ABSTRACT: Experimental results were obtained characterizing the plastic deformation flows in a series of steels and copper under repeatedly varying load conditions both homogeneous (tension-compression) and nonhomogeneous (shear). The types of steels used were: low carbon steels 20Kh and 25, medium carbon steel 45, and high-temperature austenitic steels 1Kh18N9T, 1Kh18N10T, and EI726. For symmetric tension-compression tests a hydraulic machine type TsDM-FU-10 was used and for symmetric bending—a resonance fatigue machine. The results were obtained on oscillographs in the form of hysteresis loops. The results of these tests show that the ratio of fatigue strength to a characteristic static strength in tension in metals does not

Card 1/2

I 33536-65

ACCESSION NR: AP5006989

remain constant. The cyclic deformation curves in these metals differ considerably from the static deformation diagrams. A good correlation was found between the fatigue strength in bending and tension-compression and the cyclic proportionality limit δ_{-1}/δ_{pp} . The ratio δ_{-1}/δ_{pp} varied between limits 0.8-1.0. Finally, there was a monotonic increase in plastic deformation per cycle as a function of the stress. Orig. art. has: 7 figures, 3 tables, and 1 formula.

TITLE: Particular effects of porosity on mechanical properties of iron

SOURCE: Prikladnaya mekhanika, v. 1, no. 5, 1965, 60-65

TOPIC TAGS: solid mechanical property, iron, sintered metal, metal powder, metal property, porosity

ABSTRACT: Basic results are described which were obtained when examining the physical-mechanical properties of samples of sintered iron whose void fraction varied from 0 and 50%. The experiments were carried out with a large number of samples prepared from one batch of powdered iron using a single method which allowed a comparison of results. The mechanism of destruction of material has been studied using three methods. Tensile and torsion diagrams were made. Elastic constants, plasticity and tensile strength characteristics, and electric conductance of material were determined. Bending with twisting was also investigated. An analysis of the effect of porosity on various properties was also performed. Also, experiment were performed to determine the affect of oxide films on the surfaces of the walls of exposed pores on the shape of the tensile diagram. TITLE: Fatigue limit of axle steel in the forced-fit zone at low temperatures

SOURCE: Zavodskaya laboratoriya, v. 31, no. 7, 1965, 859-862

TOPIC TAGS: fatigue limit, axle steel, forced fit zone, low temperature, dynamic loading machine, stress concentration, hot working, cold working, surface hardening

ABSTRACT: The fatigue characteristics of metal with stress concentration in its forced-fit zone at low temperatures have so far been relatively uninvestigated. In most cases this is due to the experimental difficulties and the lack of apparatus that could assure the required range of low temperatures during prolonged tests of dynamically loaded specimens. The literature contains little information on such problems as the effect of the regime of hot and cold working on the fatigue strength of steel in the forced-fit zones of axles, shafts, and other elements operating at normal and low temperatures. It has recently been determined, however, that surface hardening is one of the most effective methods for the cold-

Card 1/3

L 57734-65

ACCESSION NR: AP5017094

4

working of elements that have stress concentrations and are exposed to cyclic loads. In this connection, the authors investigated the fatigue strength of hardened and nonhardened specimens of axle steel (0.42% C, 0.8% Mn, 0.3% Si, 0.1% Cr, 0.1% Ni, 0.18% Cu, 0.027% S, and 0.014% P) at normal (+20°C) and low (-60°C) temperatures. The specimens were of 30 mm diameter and had stress concentrations in their forced-fit zone. Nonhardened smooth specimens of 8 mm diameter, as well as specimens of the same diameter with annular grooves also were tested.¹⁾ The specimens were heat-treated by the standard procedure used in the production of locomotive axles and cold-worked by means of a special three-roll lathe attachment. Their fatigue tests were then performed in two dynamic loading machines equipped with a special cooling system for testing at low temperatures. An analysis of the findings showed that the method of hot and cold working and the ambient temperature markedly affect the fatigue strength of axle steel, particularly in the forced-fit zone. Hardened specimens displayed a 32% higher fatigue strength. As the temperature decreased to -60°C the fatigue limit of axle steel following 10⁷ loading cycles was somewhat higher than at room temperature. Thus, yet another proof was obtained that hardening has a greater effect on fatigue strength than any other type of treatment. Thus while the physical nature of the process of the increase in the fatigue strength of metal in the zone of its limited endurance at low temperatures still remains unclarified, it is perfectly obvious that the

Card 2/3

L 5773A-65

ACCESSION NR: AP5017094

change in the fatigue limit is preceded by a series of factors of a technological nature. The positive influence of the hardening effect on endurance in the zone of high overloads also is incontestable. Orig. art. has: 3 figures, 2 formulas.

stability, oxidation resistance at high temperatures, etc. The apparatus consists of a gas dynamic test bed, a high-temperature flow generator (from 600 to 3000K), and an instrumentation complex for measuring and recording the flow temperature and other parameters. The gas flow can attain velocities up to Mach 1.5 at a flow rate of 1.7 kg/sec, and pressures of 80 newtons/cm². The air stream is heated successively in three combustion chambers and pumped through a blow-through chamber. Three types of blow-through chambers are used as test sections: one for a continuous test run, another for a controlled duration test run, and a third type for instantaneous exposure and removal of the model. The instrumentation consists of thermocouples, automatic recording potentiometers, calorimeters, pyrometers, oscillograms, and flow meters. The apparatus also contains a device for controlling the mixture of the test gas. Orig. art. has: 4 figures.

TITLE: Fracture of high-temperature alloys under thermocyclic loads

SOURCE: Poroshkovaya metallurgiya, no. 2, 1966, 69-86

TOPIC TAGS: oscillograph, alloy, cyclic load, heat transfer, material fracture, turbine
blade, nickel base alloy / N-700 oscillograph, 1Kh18N9T alloy, EI607 alloy

ABSTRACT: Studies on the thermal fatigue of real gas-turbine nozzle blades made of a Ni-
base alloy were carried out on a gas-dynamic test rig. The blades were heated in a gas flow
(373 \approx 1173°K and 373 \approx 1473°K) temperatures, pressures and velocities and cooled in a flow
of compressed air, which corresponds to the conditions of service of turbine blading during tur-
bine startup and shutdown. The periodic connection and disconnection of the combustion chamber
produced near-natural heating and cooling cycles. The flow rate of hot gas in front of the
leading edges of the blades was 120 m/sec. The temperature field over the blade cross section

Cord 1/3

L 44362-66
ACC NR: AP6007290

was investigated with the aid of chromel-alumel thermocouples and recorded on photosensitive paper with the aid of a N-700 oscillograph. Analysis of the oscillograms revealed (Fig. 1)

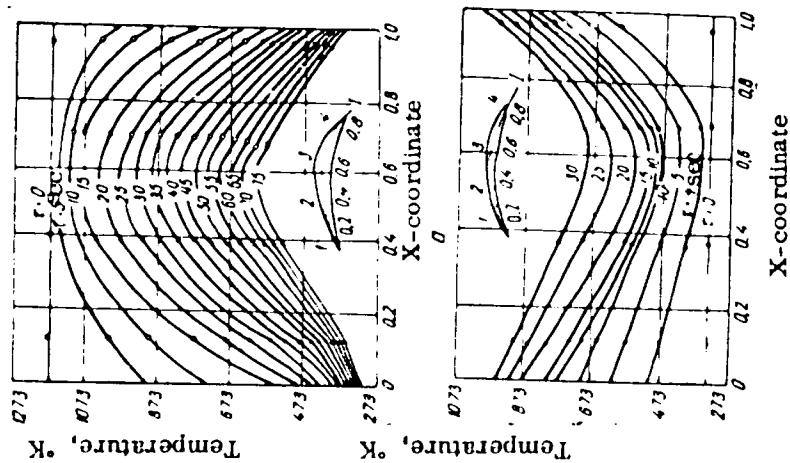

Fig. 1. Experimental curves of temperature distribution over the mean cross sectional area of turbine blades made of Ni-base alloy;

a - during cooling; b - during heating

Card 2/3

L 443-6
ACC NR: AP6007290

that the heating and cooling rates differ for the leading and trailing edges of the blades and hence the temperature stresses also differ. Calculations performed by the method of successive approximations showed that the concomitant plastic deformations produce residual stresses which cause the metal to flow alternately in one direction and another. These reversals of the flow of metal due to temperature-induced stresses transcend the yield point of the material at a given temperature and, following a comparatively small number of heat transfers, lead to the formation of cracks at the metal surface and hence also reduce the metal's strength. Thus, e.g. tests of the nozzle blades cyclically heated in the temperature regime of $373 \approx 1173^{\circ}\text{K}$ led to no cracks following 150 heat-transfer cycles, but when performed in the regime of $373 \approx 1473^{\circ}\text{K}$ they resulted in the formation of a network of fatigue-type cracks on the blade edges after as few as 40 heat-transfer cycles. Formulas relating the irreversibly absorbed energy W per thermal (heat transfer) loading cycle to the number N of these cycles are derived and employed to predict the number of cycles until fracture, and hence also the service life of such alloys as Kh18N9T and EI607, as confirmed by experimental findings. Orig. art. has: 10 figures, 60 formulas.

TITLE: The general case of transverse vibrations in a rod with variable cross section taking account of dissipation of energy in the material

SOURCE: AN UkrSSR. Institut problem materialovedeniya. Rasseyaniye energii pri kolebaniyakh uprugikh sistem (Energy dissipation during vibrations of elastic systems). Kiev, Naukova dumka, 1966, 19-31

TOPIC TAGS: vibration analysis, heat energy conversion

ABSTRACT: The article starts with a consideration of transverse vibrations which are symmetrical with respect to the axis of the system. It is assumed here that the ratio of the length and the transverse cross sections of the system is such that, in setting up the differential equation for the transverse vibrations of such a rod, account must be taken of the rotational inertia of its mass as well as the transverse force. To derive the differential equation for the transverse vibrations of a rod with a variable cross section with a cross section area $F(x)$ and a bending rigidity of the section $EJ(x)$, we isolate an element of the rod with a length dx which carries out a complex motion, consisting of forward motion parallel to the y axis and a rotating

Cord 1/2

L 07580-67

ACC NR: AT6029363

motion in the plane of the vibrations (in the xy plane). The remainder of the article is an extended mathematical development, arriving at formulas which permit construction of the resonance curve of the transverse vibrations of a rod whose cross section varies along the length in an arbitrary manner. ORG: Institute of the Problems of the Science of Metals AN URSR (Institut problem materialoznavstva AN URSR)

TITLE: Investigation of the damping properties of some refractory metals at high temperatures in vacuum

SOURCE: AN UkrSSR. Dopovidi, no. 11, 1966, 1417-1422

TOPIC TAGS: vibration damping, refractory metal damping ability, molybdenum vibration damping ability, tungsten vibration damping ability, niobium vibration damping ability, refractory metal

ABSTRACT: In a search for a material possessing high damping characteristics at high temperatures, the Laboratory of Vibrations of the Institute of Problems of the Science of Materials AN URSR has investigated the damping behavior of as-rolled and annealed (1173K for 1 hr) sintered molybdenum, arc-melted niobium, and sintered tungsten. Flat specimens were subjected to vibrations under a stress varying from 200 to 300 mm/m² in a vacuum at 293—1500K and in air at 293K. The logarithmic decrement of vibrations was used as a criterion of the damping ability. In all the tested materials and at all test temperatures, the decrement increased with

Cord 1/2

ACC NR: AP6036827

increasing stress. The decrement of the tested metals, except molybdenum in the as-rolled condition, increased with increasing test temperature. For almost all the tested metals in the entire range of test temperatures, the values of the decrement on heating differed from those on cooling. At 273K, the damping properties of metals before heating were, as a rule, slightly higher than after heating. The magnitudes of the decrement in vacuum and in air at 273K differed by 6-8%, with the difference decreasing as the decrement increased. At all test temperatures, refractory metals had a higher decrement of vibrations than the most heat-resistant nickel-base alloys. Satisfactory damping properties combined with a high endurance limit (as compared with heat-resistant alloys) in the wide temperature range make refractory metals promising structural materials in various fields of modern industry. TITLE: Investigation of lubricants in hot extrusion of steel ✓

B

SOURCE: Kuznechno-shtampovochnoye proizvodstvo, no. 4, 1966, 11-13

TOPIC TAGS: steel extrusion, hot extrusion, extrusion lubricant, glass lubricant, glass lubricant deposition

ABSTRACT: Twenty different glass lubricants have been tested in hot extrusion of 1Kh18N9T steel ingots. The chemical composition of some of the glass lubricants is shown in Table 1. The ingots were heated for 10 min to extrusion temperature in a molten glass bath. This method of heating and applying glass lubricant was found to have a number of advantages. It raises the effectiveness of extrusion, reduces the nonuniformity of heat distribution in the ingot, and ensures a strong adhesion of lubricant to the ingot surface. The glass lubricant also increases the plasticity of the surface layer of the metal, which resulted in a better surface quality of extruded articles. Lubricants no. 12, 13, or 16 also reduce the extrusion pressure. The thickness of the glass layer depended upon glass viscosity and varied from 0.65 to 1.3 mm with low viscosity glasses to 2.8—5 mm with high viscosity glasses. Best results was obtained with glasses no. 13 and 16. The softening temperature of

SOURCE: Zhurnal analiticheskoy khimii, v. 21, no. 6, 1966, 669-672				
TOPIC TAGS: photometric analysis, niobium, niobium containing alloy, alloy steel				
ABSTRACT: A rapid photometric method for determining 0.03-2.5% niobium in alloy steels is described. In this method, the steel sample is first dissolved in sulfuric acid and the niobium content is determined photometrically, using sulfochlorophenol S (solution in 3N HCl containing tartaric and phosphoric acids) as indicator. The structure of the sulfochlorophenol S indicator is

TITLE: Enzyme synthesis of glucosamine in liver under hyperoxidation

SOURCE: AN SSSR. Doklady*, v. 154, no. 1, 1964, 220-222

TOPIC TAGS: glucosamine, glucosamine synthesis, enzyme, enzyme synthesis animal tissues, in vivo analysis, in vitro analysis, fructose 6-phosphate, ammonium ions, hyperoxidation, liver preparation, brain preparation

ABSTRACT: The possibility of the synthesis of glucosamine by enzymic liver preparation from fructose 6-phosphate and ammonium ions is investigated. Glucosamine could be synthesized in a system containing an enzyme, hexophosphate and glutamine or ammonium chloride. The experimental conditions are given and it is established that the synthesis is most intensive during the first 30 minutes. The volume of glucosamine synthesis from glutamine is 0.22μ mole/hour ml, from

Card 1/2

ACCESSION NR: AP4010766

ammonium chloride about 0.16μ mole/hour ml. The experiments consist of two parts: (1) exposure of the animal to an increased oxygen pressure, (2) preparation of an enzymic preparation and the determination of its activity under usual gas conditions. It is found that after the action of oxygen the glucosamine content is 49% lower than in the control sample. The enzyme is affected by hyperoxidation and a comparison of the metabolisms in the liver and brain shows that the liver synthesizes glucosamine predominantly and the brain consumes it.

TITLE:

The cosmic-ray equator according to the data
obtained with the third Soviet spaceship

SOURCE:

Akademiya nauk SSSR, Iskusstvennye sputniki Zemli,
no.11, Moscow, 1961. Rezul'taty nauchnykh issledovanii, provedennykh vo vremya solet'ya v orbitu
i tret'yego kosmicheskikh korabley-sputnikov, 30-74

TEXT: It is pointed out that the use of satellites in
determination of the cosmic-ray equator, i.e. the geographical
position of the line of minimum intensity of primary cosmic rays,
has many advantages over terrestrial measurements. In a previous
paper the authors reported the determination of 22 points on this
equator with the aid of the second cosmic Soviet spaceship in
only 20 hours!. The apparatus mounted on the third spaceship
included a gas-discharge naissen - 1 (SGS-5) counter and a
scintillation counter (NaI:Ti). The counters were placed inside
the spaceship and were surrounded by a screen of between 7 and

Card 14

The cosmic-ray equator ...

150 g cm⁻², as described by S. F. Papkov et al. (Ref.2: Iskusstvennyye sputniki Zemli, No.9, Izd-vo AN SSSR, 1961, p.70). Pulses from the counters were fed into scaling circuits which were sampled at intervals of 3 min by a memory device with a capacity of 24 hours. In this way it was possible to measure the latitude dependence of the intensity of cosmic radiation for each transit across the equator. It is noted that the cosmic-ray intensity measured by the STS-5 counter in the polar regions and at the equator (3 particles cm⁻² sec⁻¹ and 0.7 particles cm⁻² sec⁻¹, respectively) is in excess of the published values for this intensity (Ref.3: A.N.Charakhch'yan and T.N.Charakhch'yan, ZhETF, 35, 1088, 1958). An analogous effect was observed from the second cosmic spaceship. The discrepancy may be due (among other things) to secondary radiation produced in the envelope of the spaceship. Fig.5 shows the position of the cosmic-ray equator obtained by averaging the data obtained with the second and third spaceships. It follows from this figure that the cosmic-ray equator at altitudes of 200 to 300 km is in satisfactory agreement with the equator computed by J.J.Quenby and W.R. Webber (Ref.7: Philos.Mag., 4, 90, 1959) and the octupole-approximation calculations of

TABLE I. Dosimetric measurements made during the second Soviet space vehicle, launched on August 20, 1975, from Baikonur Cosmodrome. The vehicle was equipped with two scintillation counters and two external counters. One of the scintillation counters was attached to the external counter and was used for re-entering soft electrons with an energy of 1-10 keV. The other scintillation counter, used for registration of charged particles, and the TEP-1^a (TSS-1) and TEP-2^b (STS-2) external counters were installed inside the vehicle during the capsule separation. The results of radiation intensity measurements of the flight trajectory are shown in fig. 1. An analysis of the section of the flight trajectory are shown in fig. 1. An analysis of the radiation field of the external scintillation counter shows that 1/3 of the radiation is registered during re-entry, 1/3 during the orbital phase and 1/3 during the reentry phase.

Card 1/8

Dosimetric measurements on ...

Fluence $\varphi_{\text{tot}} = 1 \times 10^{-10}$ ev/cm² sec. was approximately equal to the dose of radiation absorbed within the vehicle's interior, which was about 1 mrad per day. Radiation measurements in the areas of the equator, 30° N, and 30° S were shown to consist of secondary-ionized charged particles and γ -radiation with a mean energy of not more than ~ 10 kev. Since, with increasing latitude, these readings change by approximately the same degree, this result also holds true for the polar regions. An analysis of the results has established that the radiation belts were located nearly 10 km from the Earth's surface. A figure is included showing the variation, latitude, of the intensity of absorbed radiation over different areas of the Earth. The highest quantity of absorbed radiation (10 mrad/day) was registered near the coast of Brazil. The presence of protons suggested that this region is part of the inner radiation belt. Discussing the composition of the total absorbed dose, the authors state that 20% of it consisted of primary radiation, secondary charged particles of cosmic origin, 10% consisted of γ -radiation, γ -radiation, and 5% of protons in the inner radiation belt. The values of RBE for the last two components were no greater than 1 and 10 respectively. The RBE value for charged cosmic particles is accepted as 7 (see table).

S/560/01/000/002/007/000

D045/D114

Radiometric measurements on ...

could not be obtained), the biologic equivalent of the absorbed dose registered on the second space vehicle will be equal to 40 mrem/day. If the correction for the tissue non-equivalent of the crystal of sodium iodide is taken into consideration, the absorbed dose will be equal to 50 mrem/day. The following conclusions were drawn: (1) The absorbed dose of 7 mrad/day, equivalent to 50 mrem/day, can be considered safe for long flights along a trajectory similar to that of the second Soviet space vehicle during the period when the Sun is in its quiet state. It is assumed, of course, that an astronaut will be protected by a layer of substance similar to that around the radiometric equipment on board the second space vehicle; (2) Chromospheric flares on the Sun can essentially increase the dose. . . . I. Papkov, A. F. Tupikin, G. I. Bol'shakova, L. K. Bocharov and S. V. Vasil'ev are mentioned for their cooperation in the work. There are 2 figures and 10 references: 7 Soviet-bloc and 3 non-Soviet-bloc. The English-language references are: J. A. Simpson, Astrophys. J. Suppl. Series, 4, 177, 1958; R. L. Arnould, R. A. TITLE: Radiometric equipment on the second Soviet space vehicle.

SOURCE: Akademika nauk SSSR. Issledovaniya v selenovedeniye. Sov. Akad. Nauk. Moscow, 1961, 78-89

TEXT: Radiometric equipment installed on the second Soviet space vehicle for measuring the intensity of ionizing radiation and for detecting charged particles is described. A block diagram of the transmitter system is given in Fig. 1. The scintillation counter (A) registered (1) charged particles penetrating the walls of the vehicle, (2) γ -quanta of more than 1 k-eV, and (3) the energy release of the above-mentioned particles. The PTS-5 discharge counter (B) registered charged particles. The scintillation counter (C) measured the energy flow of comparatively slow charged particles. The operational theory of the transmitter system, separate receipts of the instruments, and the off-scale factor of the ionization chamber are given, respectively.
